I INTRODUCTION

The TT (Thirty-two/Thirty-two bit) is the first member of a new series of Atari computers designed as enhanced versions of the existing ST and MEGA family. The TT series maintains compatibility with the ST/MEGA architecture, but uses the Motorola 68030 microprocessor and provides enhanced graphics and sound. The TT is also designed to allow it to run UNIX 1 without any speed penalty caused by ST compatibility constraints.

The TT series are based around the high performance 32-bit Motorola MC68030 processor running at a 16 MHz clock frequency. The 68030 includes onchip data and instruction caches which can be filled from some regions of memory in bursts of double word fetches.

The architecture also includes the industry standard VMEbus to facilitate expansion. The system supports the latest revision (C.1) of the VMEbus specification. The TT can accommodate one single-Eurocard VME board.

The TT series is expected to function in an environment with other TTs and even machines from different manufacturers. To facilitate connectivity, each system has an on-board port for a moderate speed LAN. If the LAN is not being used, the port can be programmed to be a standard RS232C port. Through an optional VMEbus-based or SCSI-based Ethernet controller, the TT also has the capability of connecting to heterogeneous Ethernet networks. Additionally, each TT has three standard RS-232C serial ports for connection to modems, display terminals, or digitizing tablets.

The TT is intended for use with either TOS or the UNIX operating system. The initial UNIX product offering is based around UniSoft's UniPlus+ V Release 3 version 1 which is fully compatible with AT&T System V Interface Definition (SVID), the Portable Operating System Interface Specification (POSIX), and the X/Open Portability Guide. The X Window System, a network transparent window system originally developed at MIT, will also be available in the initial release. A windowing user interface running on top of X will also be provided.

The hardware features of the TT series of computers includes:

- Motorola MC68030 at 16MHz
- Motorola MC68881/68882 Floating Point Coprocessor
- RAM: 2 Mbyte of dual-purpose (video/system) RAM, expandable by an addon daughterboard containing an additional 2 or 8 Mbyte of dual-purpose memory. This memory appears 64-bits wide to the video logic and 32-bits wide to the rest of the system. TT video logic requires access to this memory on a time critical basis. The remaining system logic, including the processor, can access this memory in the alternate 250 nS time slices.

RAM: 4 Mb nybble-mode memory daughter-board(s) allowing another 4Mb or 16Mb expansion.

Unix is a trademark of AT&T.

- ROM: 4 socketed 1 Mbit ROMs, providing 512Kb of ROM space. All four ROMs must be present, because of the 32-bit wide system bus access.
- internal video modes that are a superset of those in the Atari ST series Color: 320x200x16, 320x480x256, 640x200x4, 640x480x16. DuoChrome: 640x400. Monochrome: 1280x960.
- an analog RGB color monitor interface (for color and DuoChrome modes)
- a high performance ECL monitor interface (for the high resolution monochrome mode)
- parallel I/O port, implemented using the one of the parallel ports on the General Instruments AY-3-8910 / Yamaha YM-2149 sound chip
- internal speaker, that can be disabled under software control
- 2 async serial I/O ports (one from each of two 68901 MFPs)
- 2 high-speed SDLC serial I/O ports (from a Zilog 8530 SCC), one port of which can be programmed to be a LAN interface with a proprietary single channel DMA controller
- real time clock (RTC) with 50 bytes of non-volatile RAM
- ST/MEGA compatible intelligent keyboard, with mouse and joystick ports, with support for up to a 3 button mouse
- Atari ACSI DMA channel (for Atari Hard Disk, Laser Printer, CD-ROM, etc)
- floppy disk controller and interface sharing the ACSI DMA channel
- Musical Instrument Digital Interface (MIDI)
- Atari ST compatible cartridge port (128 Kbyte storage)
- SCSI interface using 25-pin connector implemented with the NCR 5380 SCSI controller chip and a proprietary DMA controller
- VMEbus for expansion: TT contains 1 single Eurocard A24/D16 and A16/D16 slave only interface

II MAIN SYSTEM

The TT architecture is designed to be a high performance computing platform. By including the VMEbus and facilities for multi-processing the system can be expanded for future needs.

II.1 Processor and MMU

The TT uses the Motorola MC68030232-bit microprocessor. This single chip contains a 68020 superset processor, a paged memory management unit, and independent instruction and data caches. The 68030 is a complex instruction set computer (CISC) that extends the 68000 instruction set and enhances the addressing modes. The processor will be clocked at 16 MHz.

The MMU in the 68030 is a subset of that provided by the Motorola MC68851. In particular, the translation look-aside buffer (TLB) has been reduced to 22 entries, requiring particular care in memory assignment to avoid unnecessary descriptor thrashing.

The on-chip instruction and data caches maximize processor throughput while reducing the bus bandwidth necessary to fuel the processor.

II.2 Floating Point Coprocessor

The TT includes a socketed Motorola MC68881 Floating Point Coprocessor. The MC68881 can be removed and replaced with the hardware compatible MC68882. There is a slight software difference in the size of the exception stack frames, but it is possible to write software that will run transparently with either part.

The floating point operations are performed in accordance with IEEE Standard 754, with both 32-bit (single) and 64-bit (double) precision external access.

The floating point coprocessor is run at the same clock speed as the main processor. It appears as the "standard" floating point coprocessor ID of 1 in the 68030 CPU address space.

II.3 ROM

The system includes on-board sockets for a set of four 1Mbit ROMs, providing a total of 512Kb ROM. Since system bus access is 32-bits wide, all four ROMs must be present. Jumpers are provided to allow the use of 27256, 27512, 27010/27C1001, and 57101/27C1000 EPROMs, in addition to 53100 ROMs. The default jumper position allows the use of 27512 EPROMs (for a total of 256 Kb of ROM) as well as 571001/27C1000 EPROMs or 531000 ROMs (for a total of 512 Kb of ROM). 32 pin sockets are provided, although 27256, 27512, and 531000 only use the bottom 28 pins.

An image of the first 8 bytes of ROM resides in the first 8 bytes of the ST compatible image. These first 8 bytes (0x0000000-0x000007, or 0xFF000000-

2 MC68030, MC68020, MC68851, MC68881, and MC68882 are trademarks of Motorola, Inc

0xFF000007 in the image) are accessible *only* in supervisor mode. Attempts to read from this area in user mode, or any write, results in a bus error. A VMEbus master would have to do a privileged accesses to read the ROM at these locations. The full ROM resides at the memory location 0x00E00000 - 0x00EFFFFF (with an image at 0xFFE00000 - 0xFFEFFFF).

Among the tasks this ROM perform are system initialization, power-on diagnostics, and boot code from a floppy, ACSI device, or SCSI device.

II.4 RAM

The basic system includes 2 Mbytes of dual-purpose RAM which is used for both video and system memory. This is implemented by using 16 256Kbitx4 100 nS DRAMs, yielding a 64-bit wide internal bus for high performance video access.

The bus architecture is similar to the ST in that memory access cycles are interleaved between the MPU and the video controller in 250 nS RAM time slices, thus allowing video display memory to reside efficiently as part of main memory. During active display cycles the processor is prevented from accessing the memory but is allocated the next 250 nS time slice. The processor interfaces to this RAM through a 32-bit bus, but the video subsystem itself accesses memory on a 64-bit wide bus. The video chip (TT shifter) has on-chip buffering to provide very high bandwidths for data.

Single-purpose RAM daughter-boards are possible as an option. By eliminating the video timing constraints on this RAM, this memory can be made to appear faster to the processor. The daughter boards are currently implemented by using 32 1 Mbit 100 nS DRAMs. When 4 Mbit DRAMs become available, it will be possible to provide 16 Mbyte of single-purpose RAM on a single daughter card. The single-purpose memory system uses nybble mode RAMs to facilitate burst mode filling of the 68030 caches.

Additional memory can be installed in the system by plugging in a VME memory card. The VME RAM will run slightly slower than the system RAM as all VME accesses incur an extra wait state per bus cycle.

The first 0x800 bytes (2K) of RAM (0x0000008-0x000007FF, or 0xFF000008-0xFF0007FF, in the image) are accessible only in supervisor mode. Attempts to read or write to this area in user mode results in a bus error.

11.5. System Control Unit

The System Control Unit (SCU) provides an additional level of interrupt control for the system. It also contains registers that allow the software generation of interrupts. All of the SCU registers are reset at power-on and by the reset pushbutton.

II.5.1 Interrupt Mask and Current Status

The SCU contains two mask registers that permit independent control over which interrupt levels will be seen by the processor. One register masks interrupts generated on the system board and the other masks VMEbus sources. These registers are cleared at power-up or reset, disabling all interrupts.

There are also interrupt request registers that show the current state of the seven interrupt request levels from each of the sources. This register shows the physical status of the interrupt lines before they are ANDed with the SCU's mask register.

The motherboard sources for IRQ5 and IRQ6 can be serviced by either the 68030 or the VMEbus master. The implementation used means that IRQ5 and IRQ6 look to the 68030 like VME interrupts, and can not be masked independently with the SCU motherboard interrupt mask register.

II.5.2 System Control Registers

The SCU also contains two read/write registers that can be used for system configuration information.

II.5.3 Interrupt Generator

The system can write to an I/O address to generate a low priority (level 1) interrupt to the 68030. This I/O address contains a read/write status/control port, only the least significant bit of the least significant byte is defined. When set to 1, it generates an autovectored level 1 interrupt. When cleared, the interrupt request is taken away.

- KA

- 14

The SCU is hardwired so that:

- only interrupts 5 and 6 have external IACK pins and are capable of generating vectored interrupts on the motherboard (and also cause VME IRQ5 and IRQ6 respectively)
- SCU generated IRQ1 and IRQ3 are hardwired to the corresponding priorities and are always autovectored
- SCU generated IRQ1 is detected only by the MPU not the VMEbus
- VMEbus SYSFAIL generates a system (motherboard) IRQ7 to the MPU, but does not not generate an IRQ7 to the VMEbus. The only other source of an IRQ7 is a BMEbus card.

II.5.4 Bus Timer

The SCU also implements a system bus timer. If nothing concludes a bus cycle within 16 microseconds, the SCU will signal a bus error.

II.6. DMA Controllers

The TT series includes three independent DMA channels: 1) the low speed network port implemented on SCC serial port A, 2) the SCSI port and 3) the ST "ACSI"/Floppy DMA. The following are the DMA bus mastership priorities:

priority	function
highest	ACSI/Floppy Controller
	SCC DMA Channel
	SCSI DMA Channel
lowest	68030

II.6.1 SCC and SCSI DMA Channels

The SCC and SCSI DMA controllers assemble the bytes from the peripheral into double words for writing to the system bus. This feature is actually implemented with two independent "assembly" double words so that when one has been filled and is waiting for access to the processor bus, the second can be filling. If the second assembly word fills before the bus is released by the DMA chip, it will be written in the same bus transaction.

DMA can be done to any byte boundary of any double word wide memory space, either on the main system board or on the VMEbus. DMA is done in the physical address space. The programmer's model of each of these DMA channel consists of:

- a word wide read/write status/control register that contains direction. enable and bus error bits
- four bytes forming a 32-bit DMA pointer.
- partial input register that must be read and merged with RAM contents under CPU control if the DMA input is done to a point in RAM that is not on a double word boundary or if DMA is not done in multiples of four bytes,
- a 32-bit wide DMA byte count (implemented in four separate bytes).

A DMA controller exists for each channel: SCC and SCSI. Each DMA controller is physically implemented in two chips: one for the system bus interface, one for peripheral interface and FIFO. The bus interface controller is strapped externally for either SCSI or SCC.

The software that sets up the DMAC for DMA transfers must account for the DMAC being a byte-wide peripheral appearing on the odd bytes of the address bus. This requires the 68030 either to use the MOVEP instruction or to do rotates and four separate byte output operations to put out a 32-bit address or byte count. DMA Controller Registers

- offset width function
- Ox00 OB DMA Pointer Upper
- Ox02 OB DMA Pointer Upper-Middle
- Ox04 OB DMA Pointer Lower-Middle
- Ox06 OB DMA Pointer Lower
- Ox08 OB Byte Count Upper
- Ox0A OB Byte Count Upper-Middle
- OxOC OB Byte Count Lower-Middle
- Ox0E OB Byte Count Lower
- Ox10 W Data Residue Register High
- Ox12 W Data Residue Register Low
- Ox14 OB Control Register

The control word is a bit-mapped register:

- bit function
- 0 DMA Direction Out (1 = out to port)
- 1 Enable (0 = off, 1 = on)
- 2-5 <reserved>
- 6 Byte Count Zero (1 = terminal count)
- 7 Bus Error (1 = Bus Error occurred during DMA by this channel)

To perform DMA:

- 1) set the DMA controller direction
- 2) set the base address

3) set up the peripheral for DMA

4) then set the enable bit

The direction and enable bits should not be set in the same operation.

If DMA input is done to anything but a double word aligned destination, or if the length is not a multiple of 4, the final byte(s) of the transfer will not be written to the system RAM. It is then the programmer's responsibility to read the Data Residue Register and merge the input with the contents of the appropriate double word in RAM. (The least significant two bits of the DMA pointer are correctly incremented, which can be used to determine how much of the Residue Register is valid.)

DMA can only be done to double word width ports, like RAM and D32 VME cards.

If an attempted DMA operation generates a bus error, the DMA operation is immediately disabled and the bus error bit set in the Control/Status register. The bus error status bits of each of the DMA controllers routed to individual MFP-2 input bits where they can be read or optionally used to generate an interrupt. The bus error status for a channel is automatically cleared by reading the channel's control register.

The DMA byte count register generates an interrupt when the byte count reaches 0. The DMA is automatically disabled by reaching the terminal count.

The NCR 5380 SCSI Interface Chip must not be used in BLOCKMODE DMA for use with the TT DMA controllers. The SCC should be in programmed to use the WAIT/*REQ pin in *REQ mode when doing DMA.

II.6.2 Floppy/ACSI Interface '

The ST compatible Floppy/ACSI subsystem interfaces between dual-purpose RAM and ACSI compatible peripherals, such as the SLM804 laser printer, SHxxx/Megafile hard disk drives, and Atari CD-ROM. This DMA channel is shared with the internal floppy disk controller.

DMA between RAM and ACSI peripherals, and between RAM and floppy, can only be performed using the dual-purpose RAM. If a transfer is required from such a device into standard ("single-purpose") system RAM, a two stage transfer is required, using the dual-purpose RAM as an intermediate buffer.

II.7 Real Time Clock

The TT system includes a Motorola MC146818A Real Time Clock chip. This provides time of day (down to one second resolution), date, and a programmable periodic interrupt. The RTC is provided with a 32.768 kHz crystal that is independent of all other system clocks.

The interrupt output of the real time clock chip connects to one of the MFP parallel inputs.

The chip also includes 50 bytes of battery backed up (non-volatile) RAM that is used for storing diagnostic and configuration data.

The chip is accessed through two consecutive word ports. The first word is a write-only port that is used to set the real time clock chip address that is desired. The second word is the read/write data port. When doing a write to a clock chip register, it is possible to do a double word write; the first word would set the address, and the second word the data.

=

III. Device Subsystems

The TT architecture supports the following device subsystems:

SCSI

ST compatible ACSI

- high-speed serial ports and a moderate speed network port through the SCC chip
- two additional serial ports and an external interrupt port connected to MFP controllers
- a Centronics parallel printer port driven by the Yamaha YM-2149 sound chip
- a ST/MEGA compatible intelligent keyboard, mouse, and joystick interface
- a port supporting application and diagnostic cartridges

III.1 SCSI

The TT implements the complete single-ended (non-differential) SCS1 bus by using the NCR5380 SCS1 Controller. The NCR5380 is used in 8-bit asynchronous data transfer up to 4.0 Mbytes/second.

The SCSI connector provides for connection of SCSI compatible devices through a 25-pin D connector. Internally, the full 50-pin cabling is used.

In a typical configuration, the SCSI bus will be used to provide the main mass storage elements of the system. The SCSI bus can also be used for removable media devices such as the Syquest cartridge drives and magnetic tape controllers. The default system hard disk will be SCSI unit 0, device 0.

The SCSI bus can support up to 7 major devices (in addition to the TT itself).

III.2 ACSI

The ACSI interface on the TT is identical to that on the ST. The biggest concern is the use of software timing loops for delays in talking to both the controller and peripherals. It is recommended that developers use Timer A of the MFP.

III.3 High Speed Serial Ports

The Zilog 85C30 SCC, a dual channel, multi-protocol data communications peripheral, is included in the TT design to provide two serial ports (ports A and B).

Port A can be used as either a network port or a standard low speed RS232C port. When bit 7 of the GI Sound Chip port A is a 0, LAN mode is selected. The input/output of Port A is routed to the appropriate connector: (1) if RS232C mode is selected, the port is connected to a DB-9P or (2) if the network port is selected, it is connected to an 8-pin mini-DIN connector. The output pins on the unselected port remain inactive.

The SCC handles both asynchronous formats and synchronous byte-oriented protocols such as HDLC and IBM's SDLC.

Port B is configured to be a low speed RS232C serial port that can be used for connecting to a modem or a local mainframe. It is pinned out on a DB-9P connector in a way that is compatible with the AT style. Modem control signals are derived directly from the 85C30 port B control lines. This port can operate with split transmit and receive baud rates.

The PCLK input to the SCC is 8 MHz. The RTxCA input is provided with a 3.672 MHz clock. The input to TRxCA comes from the low speed LAN connector. RTxCB is run at 2.4576 MHz. TRxCB is generated by the Timer C output of the second (TT) MFP.

III.3.1 SCC RS232 Port Pinout

The SCC RS232 serial ports are pinned out in DB-9P connectors in a way that is compatible with the AT sytle. On the TT, the SCC port A RS232 connections are routed to a header on the motherboard. That header can be connected with a ribbon cable to a nine pin D connector located on the VME slot cover.

SCC RS232	Pinouts	_
pin	Port A	Port B
F	(RS232 Mode)	
1	Carrier Detect (I)	Carrier Detect (I)
2	Receive Data (I)	Receive Data (I)
3	Transmit Data (O)	Transmit Data (O)
4	Data Terminal Ready (O)	Data Terminal Ready (O)
5	Ground	Ground
6	Data Set Ready (I)	Data Set Ready (I)
ž	Request to Send (O)	Request to Send (O)
8	Clear to Send (1)	Clear to Send (I)
9		Ring Indicator (I)

Note: The SCC Port B Ring Indicator (RI) signal is connected to bit 6 of the MFP-2 General Purpose I/O Port (GPIP).

III.3.2 LAN Connector Pinout

The moderate speed LAN connector is an 8 pin female mini-DIN.

SCC LAN Pinout (Port A)

- function pin
- Output Handshake (DTR, RS423) 1
- Input Handshake/External Clock 2 3
- Transmit Data -
- 4 5 6 Ground
- Receive Data -
- Transmit Data +
- 7 **TRXCA/CTSA**
- 8 Receive Data +

III.4 MFP

Two 68901 Multi-Function Peripheral (MFP) controllers are used to provide system timers, RS232C serial ports, and an interrupt controller. One MFP, designated MFP-ST, is used in a way that is compatible with the ST. It provides both a serial port and interrupt control. A second MFP provides another low speed serial port and more I/O and interrupt pins.

The baud rate clock for the MFP's serial transmitter and receiver is derived from the timer D output of each MFP. Given the MFPs' 2.4576 MHz clock, baud rates up to 19.2 Kbaud can be supported on these serial ports.

III.4.1 MFP Serial Port Pinouts

Both MFP serial pc. \exists are pinned out in DB-9P connectors in a way that is compatible with the AT. On the TT, the MFP-2 serial port is routed to a header on the motherboard. That header can be connected with a ribbon cable to a nine pin D connector located on the VME slot cover.

One of the MFP serial ports has a complete complement of modern control lines compatible with the ST, but pinned out in a 9 pin D connector. The other MFP serial port provides only a "three-wire" interface.

	MFP Serial Port Pinouts	
pin	MFP-ST	MFP-2
1	Carrier Detect (I)	
2	Receive Data (I)	Receive Data (I)
3	Transmit Data (O)	Transmit Data (O)
4	Data Terminal Ready (O)	Data Terminal Ready (O) (always on)
5	Ground	Ground
6		**
7	Request to Send (O)	Request to Send (O) (always on)
8	Clear to Send (I)	
9	Ring Indicator (1)	

The Ring Indicator (RI) signal is connected to bit 6 of the MFP-ST General Purpose I/O Port (GPIP).

III.4.2 Uncommitted I/O Pins

The least significant two bits of MFP-2's General Purpose I/O Port are not currently used and are routed to a dual row of stakes for convenience. These are simple unbuffered TTL level signals that can be used for either input or output.

III.5 Parallel Printer Port

The TT architecture includes a bi-directional 8-bit parallel printer port that implements a subset of the Centronics standard. This interface is through the General Instruments AY-3-8910 / Yamaha YM-2149 Programmable Sound Generator (PSG) chip. It is pinned out in a DB-25S in a way that is a subset of the AT. The Centronics STROBE signal is generated from a PSG bit. The Centronics BUSY signal from the printer connects to one of the parallel input lines of the MFP to permit interrupt driven printing. Eight bits of read/write data are handled through I/O port B on the PSG.

IIL6 Keyboard Interface

The TT keyboard interface is a compatible superset of the one found on the ST/MEGA computers. The keyboard is equipped with a combination mouse/joystick port and a joystick only port. The keyboard transmits encoded make/break key scan codes (with two key rollover), mouse/trackball data, joystick data, and time-of-day. The keyboard receives commands and sends data via bidirectional communication implemented with a MC6850 Asynchronous Communications Interface Adapter (ACIA). The data transfer rate is 7812.5 bits/second. All keyboard functions, such as key scanning, mouse tracking, command parsing, etc. are performed by a HD6301V1 8-bit microcomputer unit. (See the Atari Intelligent Keyboard (ikbd) Protocol, February 26, 1985.)

III.6.1 Mouse and Joystick Interface

The Atari two-button mouse is a mechanical, opto-mechanical, or optical quadnature mouse with the following minimal performance characteristics: a resolution of 100 counts/inch, a maximum velocity of 10 inches/second, and maximum pulse phase error of 50%. The joystick is a four direction switch-type joystick with one fire button.

III.7 ROM Cartridge

The TT's cartridge port is compatible with ST cartridges. The cartridge is physically connected through a 40 pin card edge connector ROM cartridge slot. Cartridge ROMs are mapped to a 128K memory region starting at 0x00FA0000, extending to 0x00FBFFFF (with an image at 0xFFFA0000 to 0xFFFBFFFF).

III.8 Video Subsystem

The TT video subsystem is designed to extend the existing ST modes. Additional modes are available on the TT that allow more colors and larger screen sizes.

III.8.1 Video Configuration

The various modes available on the TT are:

ST mode

mode	resolution	plan	es color (CLU	s palette JT entries & DACs)
00 01	320x200 640x200	4 2	16 4	512/3-bits 512/3-bits
10	640x400	ī	-	Monochrome

TT mode mode resolution planes colors palette (CLUT entries & DACs)

000	320x200	4	16	4096/4-bits
001	640x200	2	4	4096/4-bits
010	640x400	1	2	4096/4-bits (Duochrome)
011 100	<reserved> 640x480</reserved>	4	16	4096/4-bits
101 110 111	<reserved> 1280x960 320x480</reserved>	1 8	- 256	Monochrome 4096/4-bits

As the table indicates, the modes are set through either the respective (ST or TT) Shift Mode Register. In the ST mode, 16 word-wide registers comprise the ST Color Palette (also known as the Color LookUp Table - CLUT). Contained in each entry are nine-bits of color: 3-bits each for red, green, and blue. Therefore, a total of 512 possible color combinations (8 x 8 x 8) are selectable for each entry.

Mode 00 (320x200x4) can index all sixteen palette colors; while mode 01 (640x200x2) can index just the first four (Reg0 - Reg3) palette colors. The monochrome mode (10 - 640x400x1) is instead provided with an inverter for inverse video controlled by bit 0 of palette color 0 (ST Reg 0). Color palette 0 is also used to assign a border color while in multi-plane mode.

Additional resolution modes are available by programming the shifter through the TT Shift Mode register. In these modes, there are a maximum of 256 TT Color Palette Registers each containing 12-bits of color: 4-bits each for red, green, and blue. Therefore, a total of 4096 possible color combinations (16 x 16 x 16) are selectable. Through the ST Palette Bank (lowest 4 bits of the TT Shift Mode Register) one of 16 banks may be selected from the TT Color Palette for use in ST modes. This allows modes 000, 001, 010, and 100 to seemingly select from up to 256 registers by simply setting the palette bank. Only mode 111 (320x480x8) can directly index all 256 registers.

Duochrome mode is an extension of the monochrome mode found on the Atari ST. Instead of being limited to just black and white, Duochrome mode allows the display of two programmable colors. TT Palette Register 254 is normally used for the '0' color, and Register 255 is used for the '1' color. Just as in the ST, the screen colors can be inverted by setting D1 in ST (or TT) Palette Register 0.

HyperMono is a special mode that combines two of the output DACs to give 8 bits of control of the level of all three guns. The green output from the selected color palette entry provides the most significant 4 bits and the blue output provides the least significant 4 bits.

III.8.2 Video RAM/Controller/Display Interface

Video display memory is configured as logical planes (1, 2, 4, or 8) of interleaved 16-bit words of contiguous memory to form one 32,000 byte (for ST modes) or 153,600 byte (for TT modes) screen buffer starting at any 8 byte boundary (in dual-purpose RAM only). The starting address of display memory is loaded into the Video Base High, Video Base Mid, or Video Base Low Registers (the most significant byte of the thirty two bit addresses is always zero, i.e. within the ST image). This register is loaded into the Video Address Counter (High/Mid/Low) at the beginning of each frame. The address counter is incremented as the screen buffer is read.

Screen buffer is transferred to the video chip (TT shifter) buffer 64-bits at a time. The shifter then loads the video shift register where one bit from each plane is shifted out and collectively used as the index (plane 0 appears first in RAM and provides the least significant bit of each pixel) to a specific ST or TT Palette Register (depending on the Shift Mode).

III.8.3 Monitor Connector

The video output is provided on a 3 row 15 pin connector similar to the one used on standard VGA.

- Pin Function
- I Red
- 2 Green
- 3 Blue

- 12 Open
- 13 Hsync
- 14 Vsync
- 15 High Resolution Monochrome Out -

III.9 Sound Subsystem

The TT architecture extends the music subsystem presently available on the ST/MEGA computers. The TT mixes the output of the existing ST PSG sound system with a new DMA-driven dual-channel D-to-A subsystem. The TT includes an internal speaker driven by these two sources for simple beeps, and can be connected to an external stereo amplifier for high-fidelity sound.

The TT is also equipped with a Musical Instrument Digital Interface (MIDI) which provides high speed serial communication of musical data to and from more sophisticated synthesizer devices.

III.9.1 Programmable Sound Generator

The ST sound system using the General Instruments AY-3-8910 / Yamaha YM-2149 Programmable Sound Generator is present in the TT. The YM-2149 Programmable Sound Generator produces music synthesis, sound effects, and audio feedback. With an applied clock input of 2 MHz, the PSG is capable of providing a frequency response range between 30 Hz (audible) and 124 KHz (post-audible). The generator places minimal amount of processing burden on the main system (which acts as the sequencer) and has the ability to perform using three independent voice channels. The three sound channel outputs are mixed together and sent to the volume and tone control chip.

(Reference Engineering Hardware Specification of the Atari ST Computer System, page 10.)

III.9.2 DMA Sound

The DMA sound subsystem is the same as the one in the STE.

III.9.3 Musical Instrument Digital Interface (MIDI)

Musical Instrument Digital Interface (MIDI)

The MIDI allows the integration of the TT series with music synthesizers, sequencers, drum boxes, and other devices possessing MIDI interfaces. High speed (31.25 Kbaud) serial communication of keyboard and program information is provided by two ports, MIDI OUT and MIDI IN (the MIDI OUT also includes MIDI THRU data). The MIDI communicates through the MC6850 Asynchronous Communications Interface Adapter (ACIA) to the system bus. The data transfer rate is a constant 31.25 Kbaud of 8-bit asynchronous data. (Reference Engineering Hardware Specification of the Atari ST Computer System, pages 11 and 17 for more information on MIDI and theACIA.)

IV VMEbus

The TT provides the option for additional expansion by implementing the industry standard VMEbus, revision C.1. The TT has one single-high VMEboard backplane. Memory space is partitioned to allow the 68030 to access A24/D16 and A16/D16 cards.

IV.1 System Controller

System Controller

The main system board serves as the VMEbus system controller (a slot 1 "card") and implements the following functions:

- single-level (level-three) VMEbus arbiter

- IACK* daisy-chain driver
- global SYSCLK (16 MHz, independent of processor speed)
- global VMEbus time-out that drives BERR*

The level-three arbiter is designed to meet the VMEbus specification requirements.

The IACK* daisy-chain driver is designed to meet the VMEbus specification requirements.

The SYSRESET* line is driven low when (1) power-up occurs, (2) the reset pushbutton is depressed, or (3) the 68030 asserts its RESET* signal.

IV.2 Address Partitioning The TT's A24/D16 VMEbus interface is fixed at locations: 0xFE000000-0xFEFEFFFF. The A16/D16 space occupies 0xFEFF0000-0xFEFFFFFF.

IV.3 VME Interrupter

The system can write to an I/O address to generate a level 3 interrupt on the VMEbus. It can monitor a status register that indicates when that interrupt has been acknowledged and serviced. An I/O address contains a read/write status/control port, only the least significant bit of the least significant byte is defined. When set to 1, it generates a VMEbus level 3 interrupt. When cleared, the interrupt request is taken away.

Note that the level 3 interrupt must be masked off (either by setting the processor's IPL or by masking the interrupt in the system controller) or the 68030 will be immediately interrupted.

The system board responds to a VMEbus interrupt acknowledge cycle with the status ID of 0xFF.

This feature is included for compatibility with future machines in the TT series.

V Memory, I/O, & Interrupt Map

The size field has the following designations:

DW Double word

W Word wide

OD Odd byte (A byte wide port that appears in the least significant byte of the defined words. The most significant byte of the words is undefined. If desired, these ports may be accessed as bytes by adding 1 to the specified word addresses.)

EB Even byte (A byte wide port that appears in the most significant byte of the defined words. The least significant byte of the words is undefined.)

MEMORY MAP as seen by the 68030
